BIRD DIVERSITY AND THEIR HABITAT STATUS AT RAJA RANI COMMUNITY FOREST, BHOGTENY, MORANG, NEPAL

By Yub Raj Basnet Bijay Tamang Gautam Benu

Bird Conservation Nepal PO Box 12465, Kathmandu, Nepal

SUMMARY

Raja Rani Community Forest is located at Siwalik Hills, the smallest and youngest part of the Himalayas, in Morang district north of eastern Dharan forest, one of the Important Bird Areas (IBA) in Nepal. The forest is mixed type dominated by Sal *Shorea robusta*. An exploration of bird diversity was done in that area from October 2003 to July 2004. About 250-hectare was surveyed during the study period. Forest covers approximately 170 (68%) hectare, aquatic habitat covers 20 (8%) hectare, agricultural area covers 25 (10%) hectare and scrubland covers 35 (14%) hectare. Species discovery curve was calculated using Mackinnon list, with seventeen species in each list. Altogether 40 lists were prepared, 10 in each season. A total four visits were made, once in each season (i.e. autumn, winter, spring and summer).

A total of 110 bird species were recorded from the area. Hundred were resident, eight were winter visitors and two were summer visitors. Eight were nationally threatened species. Two globally near threatened species, i.e. Great Hornbill *Buceros bicornis* and probable Wedge-billed Wren Babbler *Sphenocichla humei* were recorded. Approximately 48.23% bird species were recorded from forest areas followed by 10.46% from aquatic habitat, 15.33% from agricultural area and 25.98% species from scrubland.

Although hunting is prohibited in the area by community forest management committee, collection of young chicks and illegal hunting on game bird is still prevalent. Awareness among local people might help reduce such activities.

ACKNOWLEDGEMENTS

We would like to express special thanks to Oriental Bird Club, UK for financial support without which this project would never have carried out.

We are also grateful to the local people of Raja Rani (Dhobi village), Lokhara and Naxalbari, including Tej Prasad Rai, Prasad Lama and Man Kumar Magar for their generous support.

We would also like to express our gratitude to Jiwan Sapkota, Madan Aryal, Bidur Adhikari, Chandra Basnet and Torna Basnet for accompany during the field visits.

Our sincere thanks go to Carol Inskipp for her keen interest, supports and reviews throughout the project period.

Our thanks also go to Craig Robson, Hatan Chaudhary, Hem Sagar Baral, Haris Rai, Tim Inskipp, Nabin Baral and Nilesh Timilsina for bird identification and their critical comments on this report.

We highly appreciate the help of Dev Ghimire throughout the project period.

Yub Raj Basnet Bijay Tamang Gautam Benu

INTRODUCTION

Background

Nepal has exceptionally rich and diverse avifauna. An important factor for such diverse avifauna is Nepal's varied topography and climate. The varied physiographic zones of Nepal have facilitated the country to support a high diversity of fauna and flora. In Nepal 861 species of birds are recorded (BCN 2004). Out of this, 30 species are considered globally threatened (BirdLife International 2001, 2004) and 133 species (15%) are identified as nationally threatened. Furthermore, 72 species are thought to be critically threatened or endangered (Baral and Inskipp 2004). Furthermore, 11 species are considered extinct (Inskipp and Inskipp 1991) and 78 species (59% of the total threatened) depend on forests (Baral and Inskipp 2004).

Siwaliks, the smallest and youngest part of the Himalayas, consist of a series of parallel ridges that run along the length of the country and enclose some elongated valleys (Dun). Siwalik Hills (also called Churia); has the highest percent forest cover (76%) and in terms of biogeography, least percent area in Nepal, i.e. 1,886,000 hectares (13%); are ecologically fragile and comprised of soft, very erodible sediments with steep terrain, mostly poor porous soil lacking perennial water courses (FRISP 1994).

The Siwalik region of Nepal is one of the richest areas in terms of biological diversity. The area is at the confluence of the Himalayas and the tropics, and is home to many animals and plants, and fossils, which traveled upwards from the tropics and downwards from the Himalayas. This unique area of world heritage has come under increasing threat. Humans are converting areas such as vast forest resources into agricultural and degraded land with little or no biological diversity and productivity. Valuable species are at risk (Oli 1999). Poor socio-economic condition of local communities in the Siwaliks is one of the main reasons of forest degradation and the subsequent decline in local fauna and flora.

The early Siwalik settlers had indigenous knowledge for the resource use. The traditional ecological balance between natural environment and the Siwalik Hills has changed completely (Oli 1999). It is now under threat due to the occurrence of biotic pressure, including the high population growth and high percentage of poverty (Joshi *et al.* 1996). The conservation of biodiversity in the context of socio-economic development of the people needs a comprehensive study of the biodiversity.

The Raja Rani Forest lies in the Morang Siwalik and its bird habitat is diverse due to presence of aquatic habitat in dense Sal *Shorea robusta* forest where almost all trees are covered by epiphytes. Three ponds at the southern part of forest are choked by some woody aquatic vegetation and approximately 10% of the water area is open. The area harbors many types of

aquatic as well as forest birds (Basnet 2002). People of Bhogteni, Kerabari and Letang depend on forest products for their subsistence economy. As such, forest area is gradually degrading with negative impact on bird diversity.

Objectives

The main aim of carrying out this study at Raja Rani Community Forest is to explore the avian diversity of the area. Presence of threatened as well as protected bird species in the area further signifies the study.

The broad objective is to prepare an inventory of avian diversity at Raja Rani Community Forest. The specific objectives are:

- 1. To determine the seasonal avian diversity in the area and
- 2. To assess the habitat quality of community forest for bird conservation

STUDY AREA

Location

Raja Rani Community Forest, named after Raja Rani Pokhari (pond) is situated in the Siwalik region at Bhogteny Village Development Committee in Morang district of eastern Nepal. The area located between 26°47'N and 87°26'E is situated at the height of 300-650 meters. The area is located north of eastern part of Dharan Forest, which is an Important Bird Area in Nepal (Baral and Inskipp 2001). The area lies in the west of Chisang stream, which is one of the largest streams of Morang District. Raja Rani Community Forest covers the area of about 170 hectares. Forest user groups (FUGs) have divided the forest area into four blocks for convenience, each block demarcated by brooks. The blocks were not classified according to habitat type; actually it is based on area. All the blocks have similar type of vegetation dominated by Sal. The first block lies in the northern part and is contiguous with Murchunge village. Second and third blocks are located between first and fourth block. Fourth block lies in the southern part, which is adjacent to agricultural area of Dhobi village. Three ponds that cover about 20 hectares are located between the fourth block and the agricultural area. Southern part of the Raja Rani Community Forest is contiguous with Raja Community Forest, which is separated by Bhalu Khola, a brook. Similarly, eastern part of the Raja Rani Community Forest communicates with two proposed community forests; i.e. Akashe Community Forest and Jalkaini Community Forest. Bhaiu Khola, a seasonal stream separate these proposed community forests from the Raja Rani Community Forest. Northern part of Raja Rani Community Forest is surrounded by agricultural area with the two vicinity of village named as Murchunge and Kagate. Dhobi and Lokhara are the two settlements of FUGs of the Raja Rani Community Forest that lies in the southeast of the forest area.

Climate

The area has tropical climate. Monsoon starts from June and reaches peak in July and continues through mid-September. Total mean annual precipitation was estimated to be about 2211.1 mm from 1998 to 2004 at Dharan, the nearest Metrological station from the study a rea. A verage monthly rainfall of 621.2 mm was recorded in July, while the least 3.9 mm was recorded in December during 1998-2004. Highest monthly rainfall of 929.6 mm was recorded in July 2001. Summer days are quite hot; the mean maximum temperature was recorded to be 32.7°C in May during 1998-2004. Winter is relatively cold with mean minimum temperature of 10.2°C recorded in January during 1998-2004. The absolute maximum of 34.6°C was recorded in April 1998 while the absolute minimum of 7.6°C was in January 1999. Mean monthly relative humidity varies from 74.4% to 90.8%. Annual mean maximum and mean minimum temperature, annual mean monthly rainfall and relative humidity recorded from 1998 - 2004 are shown in figure (1, 2 and 3).

Figure 1: Mean monthly temperature recorded at Dharan from 1998 to 2004

Figure 2: Mean Monthly rainfall recorded at Dharan from 1998 to 2004

Biological diversity

Flora

The principal vegetation of the area comprises of tropical evergreen forest. The tropical evergreen forest is characterized by dense vegetation with large sized trees and comparatively warm and heavy rainfall during summer. Local differences in rock types are often responsible for the tremendous variability in vegetation cover in the Siwaliks (Carson 1992).

The Community forest is mainly dominated by matured Sal *Shorea robusta* forest. Most of the trees are covered by epiphytes. Total of 43 types of orchids are recorded from the area (Basnet 2003a). The associated species with Sal are Karma *Adina cardifolia*, Amla *Emblica officinalis*, Satisal *Dalbergia latifolia*, Bel *Aegel marmelos*, Rajbrikshya *Cassia fistula* and Sahaj *Terminalia alata*.

Fauna

Wild animals found in the area are Wild Boar *Sus scrofa*, Jungle Cat *Felis chaus*, Clouded Leopard *Pardofelis n ebulosa*, Common Langur *Semnopithecus entellus*, Hare *Lepus nigricolis* and Rhesus Monkey *Macaca mulata*, Black Giant Squirrel *Ratufa bicolor* and Indian Palm Squirrel *Funambulus palmarum*. The area is very important to birds such as Hornbills, Drongos, Woodpeckers, Peacock, Jungle fowl as well as Waterhen and Froktail.

Socio-economic aspect

The study area is surrounded by villages inhabited by Brahman along with other ethnic groups such as Rai, Magar and Tamang. A total of 106 households depend on the community forest for firewood, cattle grazing, thatch grass, fodder and timber. Most of the people are uneducated and their main occupation is agriculture, animal husbandry and harvesting of forest products (Basnet 2002).

Rice Oryza sativa, wheat, corn and millet are major crops in the area whereas mustard Brassica campestris, potato Solanum tuberosum, legumes and sugarcane Saccharum spp. are grown in minor crops. Mewa Carica papaya, Amp Magnifera indica, Amba Psidium guajava, Kera Musa paradisica, Nariwal Cocos mucifera and Supari Areca catechu are the main fruits in the area.

Livestock is the major component of the agricultural system in the area. The main livestock are cattle, goat, buffalo, pig and poultry. Part of day-to-day expenditures for basic commodities, children's education and other miscellaneous expenses are borne by income generated from the sale of livestock and their products in the area.

Note: Shaded area in inset map shows Morang district and the black spot indicates study area.

MATERIAL AND METHODS

Bird Survey

Bird survey at Raja Rani Community Forest was carried out from October 2003 through July 2004. Survey was done four times once in each season (i.e. autumn, winter, spring and summer). Data were collected from different sections of community forest and it's surrounding areas. Although some observations were done from dawn to dusk, concentration was given early in the morning (06:00-10:00 hrs.) and late afternoon (15:00-18:00 hrs.) when most birds are active. All types of habitats: Sal forests, bushes and bamboo clumps, water canals, ponds and agricultural areas were covered during the survey. All the four blocks of community forest were equally visited during the survey period. Furthermore, some observations were made along the temple area and Chisang khola (stream). Total 29 days spent in study area. Number of days spent in each season is shown in table 1.

Season	Months	Date	Days spent
Autumn	Mid Aug - Mid Nov.	October 4,6,9-13, 2003	7
Winter	Mid Nov - Mid Feb.	January 13-20, 2004	8
Spring	Mid Feb - Mid May	May 3-6,10-12, 2004	7
Summer	Mid May - Mid Aug	July 4-7,17-19, 2004	7

Table 1: Total number of days spent in each season

*Seasons according to Nepali Calendar

Survey was based on direct observation. Sites concentrating bird activity, particularly water canals, fruiting trees, forests edges were watched for prolonged period. Some birds such as Blue-throated Barbet *Megalaima asiatica*, Hill Myna *Gracula religiosa*, and Red Jungle Fowl *Gallus gallus* were also identified by their calls. Binoculars were used for observation.

Observed species were recorded using Mackinnon's list. Index of relative abundance was calculated using Mackinnon's species richness counting method (Mackinnon and Phillips, 1993). A list of 17 different encountered bird species was made. This was considered as the first list. After that another new list (second list) was prepared with 17 species. Similarly, ten separate bird lists were prepared in each season. Thus, a total 40 bird lists were prepared during the whole study period. During the survey much care was taken not to repeat same species in the same list, but it was listed in subsequent lists. Observed birds were identified following handbooks Grimmett *et. al.* (2000) and Ali (1996). Finally a complete checklist was made using the observed data. Nomenclature and systematic orders of birds followed Bird Conservation Nepal (BCN) official checklist (2004).

Data analysis

Species discovery curve was plotted using Mackinnon's species-richness counting method (Bibby *et al.* 2000). The relative abundance of each species was estimated using Mackinnon's lists. Index of relative abundance was estimated based on species occurrence. The relative abundance of each species is equivalent to the fraction of lists on which a species occurs. Species occurrence was categorized into five different categories according to Index of relative abundance.

Categories	Number of Observations	Index of relative abundance
Uncommon	≤ 5	≤ 0.125
Occasional	6 –10	0.15-0.25
Fairly common	11-15	0.275-0.375
Common	16-20	0.4-0.5
Abundant	> 20	> 0.5

Table 2: Categories of species occurrence

The species were classified upto orders. Threatened status of the observed birds was also identified with the help of key books, i.e. The State of N epal's birds 2004 (Baral and Inskipp 2004). All the birds were analyzed according to its occurrence in their particular habitat type (e.g. forest type, ponds and water canals, agricultural area and open habitat of bushes with bamboo clumps i.e. scrubland).

RESULTS AND DISCUSSION

Bird Survey

Bird survey was done four times from October 2003 through July 2004. A formal discussion was done with Tej Prasad Rai, the President of Raja Rani Community Forest prior to fieldwork. Formal permission was taken for the work in the community forest. All the four blocks of the community forest were visited with the help of two local assistants. Both direct observation and call identification methods were employed to record the birds. Observation was also done at agricultural area, ponds and forest edges.

A total of 110 species were recorded that belonged to 12 orders and 36 families during a year long study period. Among the observed bird 100 species were resident, 8 were winter visitor and 2 were summer visitor. Altogether 40 birds survey list were prepared with 17 species in each list.

List number and running species

First survey was done in autumn, 2003. A total of 10-bird survey lists were prepared in seven days observation during first visit, with 17 species in each list. A total of 63 species belonging to 27 families and 11 orders were recorded from the area. An endangered species, Great Hornbill *Buceros bicornis,* was observed from third and fourth block of the community forest. Similarly three vulnerable species, Long-tailed Broadbill *Psarisomus dalhousiae,* Barred Cuckoo Dove *Macropigea unchall* and Hill myna *Gracula religiosa* were observed at fourth block of the forest. A flock of 12 Black Storks *Ciconia nigra* was also observed soaring above the fourth block near agricultural area.

Second bird survey was done in winter, 2004. A total of 71 species belonging to 26 families and 11 orders were recorded during the eight-day survey. Among them 30 species were new, which were not observed during the first visit. An endangered species; W edge-billed Wren Babbler *Sphenocichla humei* was observed from scrubland in the eastern part near Chisang khola. This might be the second record from Nepal, the first being reported from Dharan forest in 1996 (Karki and Chaudhari 1997). The bird is rare (Inskipp 2001) and also considered probable but requiring further confirmation by the Nepal Rare Birds Committee (Carol Inskipp *pres.comm*. 2005). Calls of Red Junglefowl *Gallus gallus* was recorded from third block of the forest area.

Third survey was done in late spring, 2004. A total of 64 species belonging to 29 families and 11 orders were recorded during this period. A mong them 11 species were new, which were not observed during the first and second field visits. Two Great Hornbills were observed on a fruiting Banyan tree *Ficus benghalensis* in the third block of the community forest. Again a flying individual of the same species was observed in the eastern side of Rani Pokhari, near the forest

edge of the fourth block. Three Spiny Babblers *Turdoides nipalensis* were seen in bushes in the western side of Rani Pokhari. Similarly, a Jerdon's Baza *Aviceda jerdoni* was seen in the western part of the forest near Bhalu khola. The bird is considered critically endangered (Baral and Inskipp 2004). The bird was previously reported from Patnali area of Dharan forest (Basnet *et al.* 1999, Baral *et al.* 2000, GC *et al.* 2001) and Royal Chitwan National Park near Tiger Tops Jungle Lodge (McDougal et al. 2000, Chaudhary 2000).

Fourth survey was done in summer, 2004. A total of 61 species belonging to 27 families and 11 orders were recorded. Among them 6 species were new, which were not observed during the first, second and third visits. Two threatened species, i.e. Red Junglefowl and Long-tailed Broadbill were recorded from second and third block of the community forest.

First survey Second survey		rvey	Third survey		Fourth survey		
List number	Running species	List number	Running species	List number	Running species	List number	Running species
1	17	11	67	21	95	31	107

9	61	19	90	29	103	39	110
10	63	20	93	30	104	40	110

Table 3: List number and running species

The list of birds according to orders and families as well as habitat and migratory status are shown in table 6 and appendix-I respectively. Running species was calculated with the help of list number, where number of species may increase in subsequent list. Occurrence of birds according to list is shown in table 3 and figure 5.

Figure 5: Species discovery curve

Bird diversity in different habitats

During autumn survey highest bird species (24 species) were recorded in scrubland that was adjacent to forested areas and bamboo clumps. Similarly 23 species were recorded from forest areas, 8 species each were observed from aquatic as well as agricultural area.

A total of 26 species were recorded from forest area followed by 25 species from scrubland, 13 species from agricultural area and 7 species from aquatic habitat in winter survey.

In spring 41 bird species were recorded from forest area, 11 species from agricultural area, 7 species from scrubland and 5 species from aquatic habitat.

Similarly, a total of 34 bird species were recorded from forest area, 12 species from scrubland, 8 species from agricultural area and 7 species from aquatic habitat in summer.

The number of birds in Scrubland was more in autumn and winter as compared to summer and spring. In Sal forest highest number of birds were recorded in summer. Whereas in other habitats the number of birds recorded remain almost the same.

11

	No of species				
Habitat type	Autumn, 2003	Winter, 2004	Spring, 2004	Summer, 2004	Mean %
Sal forest	23(36.51%)	26(36.62%)	41(64.06%)	34(55.74%)	48.23
Aquatic habitat	8(12.70%)	7(9.86%)	5(7.81%)	7(11.48%)	10.46
Agricultural area	8(12.70%)	13(18.31%)	11(17.19%)	8(13.11%)	15.33
Scrubland	24(38.09%)	25(35.21%)	7(10.94%)	12(19.67%)	25.98
Total	63	71	64	61	100.00

Table 4: Bird species recorded from different habitats

Approximately 48% species were recorded from forest area. It may be due to large habitat that covers about 170 hectors. Similarly 10.46% birds were recorded from aquatic habitat. 15.33% birds were recorded from the agricultural area and 25.98% birds were recorded from scrubland.

Habitat Analysis

Four major bird habitats were identified in the study area. Total 65 trees and woody vegetation were listed from the area, which were identified with the help of flora of Nepal (Shrestha 1998). Name of the major woody vegetation is given in appendix-II.

Table 5: Area, % coverage and percentage of species in different habitat.

Habitat type	Area (in ha.)	Coverage (%)
Sal forest	170	68
Aquatic habitat (ponds and streams)	20	8
Agricultural area	25	10
Scrubland	35	14

Forest Area

Mature Sal forest with low understory covers 170 hectares in the study area. Although southern and eastern part of the forest is degraded, it is dense in other areas. Bushes have replaced most of the degraded areas and are turned into scrubland with bamboo clumps. A total of fifty birds species were recorded in dense forest areas. Among them six were threatened species. One critical species i.e. Jerdon's Baza was recorded in the western part of the fourth block during the third visit.

Similarly, 13 species were observed from more then one habitat. e.g. Blue Whistling Thrush Myiophonus caeruleus and Black-backed Forktail Enicurus immaculatus were observed from

water canals in the forest. Similarly, six species were recorded both from agricultural area and forest. Six more species were listed from scrubland (bushes with bamboo clumps) as well as dense forest. 71 species utilized forest areas in total.

The southwestern part of the community forest is contiguous with proposed Raja Community Forest, A kase Community Forest and Jalkaini Community Forest, which may provide a good habitat for forest birds. All these forest areas have mature mixed Sal dominated forest. Total twenty-two *Ficus* trees also provide good fruiting trees for Hornbills.

Aquatic Habitat

Three ponds, which covers about 20-hectare provide aquatic habitat in the area. Furthermore, four rocky brooks (Bhalu khola, Dhobi khola, Lokara khola and Murchunge Khola) and one large sandy stream (Chisang Khola) provide additional aquatic habitat especially for Little Ringed Plover *Charadrius dubius*, Black-backed Forktail and White-capped Water Redstart *Chaimarrornis leucocephalus* in the area. Two species White-breasted Waterhen *Amaurornis phoenicurus* and Little Cormorant *Phalacrocorax niger* were observed mainly from aquatic habitat. Similarly, seven species such as Cattle Egret *Bubulcus ibis*, White-throated Kingfisher *Halcyon smyrnensis*, Red-wattled Lapwing *Vanellus indicus* and Indian Pond Heron *Ardeola grayii* were observed from aquatic as well as agricultural habitat.

Agricultural Area

Southeast part of the forest continues into a gricultural area and human habitation, where the FUGs live. Some patches of trees are present in the area. Approximately, 25-hectare agricultural area, which is closely associated with the forest, was surveyed during the study period. Nineteen species were recorded from the agricultural area.

Scrubland

About, 35-hectare area is covered by bushes and bamboo clumps. Such areas are mostly found at the edges of south-east part of the forest. Seven species were recorded from scrubland. An probable very rare species, Wedge-billed Wren Babbler was recorded in the eastern slope of the community forest during the second visit.

Relative abundance

Index of relative abundance was calculated using Machhinon's list. In this method, the relative abundance of each species is equivalent to the fraction of lists on which a species occurs. Among 110 bird species, three species were abundant, seven were common, fifteen were fairly common, thirty-three were occasional and fifty-two species were uncommon. During the study

period the frequency of observation of Scarlet Minivet *Pericrocotus flammeus*, Black Drongo *Dicrurus macrocercus* and Crested Serpent Eagle *Spilornis cheela* was the highest followed by Chestnut-bellied Nuthatch *Sitta castanea*, Spotted Dove *Streptopelia chinensis*, Lineated Barbet *Megalaima lineata*, Blue-throated Barbet *M. asiatica* and Red-vented Bulbul *Pycnonotus cafer*. The relative abundance of the species is shown in Table 6.

Threatened Status

Eight species recorded were threatened according to the state of Nepal's birds 2004 (Baral and Inskipp 2004). Among them Jerdon's Baza is considered critical, Great Hornbill and Wedge-billed Wren Babbler (Globally near threatened species, IUCN 2004) are in endangered category and Black Stork, Barred Cuckoo Dove, Long-tailed Broadbill, Red Junglefowl and Hill myna are Vulnerable. Both Great Hornbill and Long-tailed Broadbill were previously recorded from the area (Khanal and Yonzon 2000).

No.	Scientific Name	Categories	Block	Habitat
1.	Aviceda jerdoni	Critical	Fourth	Forest
2.	Buceros bicornis*	Endangered	Third, Fourth	Forest
3.	Sphenocichla humei*	Endangered	Degraded forest of the ea	astern slope of Fourth block
4.	Psarisomus dalhousiae	Vulnerable	Second, Third, Fourth	Forest
5.	Macropigia unchall	Vulnerable	Fourth	Forest
6.	Ciconia nigra	Vulnerable	Fourth	Forest
7.	Gallus gallus	Vulnerable	Second, Third	Forest
8.	Gracula religiosa	Vulnerable	Fourth	Forest

Table 7: List of threatened birds recorded in the study (ba	based on Baral a	nd Inskipp, 20	104).
---	------------------	----------------	-------

* Globally near threatened species

Threats

a) Pesticides (e.g. BHC, Metacid) and chemical fertilizers are used in the agricultural areas (Man Kumar Magar, President Raja Rani Pokari conservation committee, *Pers. Comm.* 2004). Birds are particularly susceptible to insecticide damage (Baral, 2000). Ingesting pesticides directly or indirectly by eating pesticide-contaminated grains, fruits, worms and insects may adversely affect them. Uses of pesticides in agricultural areas not only kill the pests but also the useful invertebrates that are the food sources of various types of birds. Some pesticides have a long term damaging effect on the reproductive process of raptors as well as aquatic birds. The sharp fall in raptor population with the increase in the use of pesticide is well known (Ratcliff 1967, Hickey and Anderson 1968, Hickey 1969). Persistent, high fat solubility and sub lethal effects are the main qualities, which lead organochlorine pesticides to cause decline in bird population. Predator and scavengers at the top of the food chain are among the most affected species (Newton 1984) as they are especially liable to accumulate organochlorines in large amounts.

b) Hunting and trapping of wild animals is prohibited. However due to lack of awareness about the importance of wildlife, it is hardly implemented. A nesting tree of Great Hornbill was cut down

in the south of Raja Pokhari during breeding period by three local people to get the beak of the female. (Lila Magar, *pers. Comm.* 2003)

Such activities are a widely observed in the western part of Siwalik Hills of Morang. Collection of young chicks of Parrots, Mynas, Peafowl, Hornbills and Woodpecker are also practiced by the local people (Basnet 2003). People from Kagate and Murchunge village, who do not permitted to utilize the forest resources, are illegally doing such activities. During the third field visit, five chicks of Indian Peafowl were seen in Dhobi village. It was taken out from its nest by herdsmen of the village to domesticate it.

c) The area is slowly developing into local tourist destination. Now the area is a popular picnic spot for the surrounding people. As such number of people visit this forested area every year. It may have adverse effect on birds' activity.

d) The forest area is the major grazing area of the cattle. So random use of forest resources may adversely effect bird population.

CONCLUSION

An exploration of bird diversity was done in the Raja Rani Community Forest area from October 2003 to July 2004 according to Mackinnon's lists. Total four visits were made in that area once in each season. Ten bird lists were made in each season which consists of seventeen species in each list. Therefore total 40 lists were prepared during whole study period.

A total of 110 species were recorded from the area. Among them 100 were resident and 10 were migratory. Bird habitats in the area were categorized according to vegetation structure and habitat types. The forest area is Sal dominated and covers approximately 170 (68%) hectares. Aquatic habitat covers 20 (8%) hectares, agricultural area covers 25 (10%) hectares and scrubland covers 35 (14%) hectares. Approximately 48.23% species were recorded from forest area. Similarly, 10.46% were recorded from aquatic habitat, 15.33% from adjacent agricultural area and 25.98% were recorded from scrubland.

The area is an important habitat for birds. Eight species of the observed birds were threatened including two Globally near threatened species. Although hunting and poaching of wild animals is prohibited in the area, collection of young chicks and illegal hunting on game birds is still prevalent.

RECOMMENDATION

The Raja Rani Community forest is an important bird site as eight nationally threatened birds including two Globally near threatened species have been recorded from the area. Therefore, the area has potential to develop into favorable site for the birds.

An inventory of bird diversity on a regular basis to find out fluctuation will help to understand the state of birds in the area.

The Great Hornbill used to nest in that area previously but now is regularly visited by Great Hornbill during fruiting period of Banyan only. Thus biological study of such species is recommended.

The flow of people into the community forest has an adverse effect on birds, so it has to be managed.

Although hunting is prohibited in the area by community forest management committee, collection of young chicks and illegal hunting on game bird is still prevalent. Awareness among local people might help reduce such activities.
